

1 **Code and data**

2 This file provides some information on how to deal with the DTM data (for the com-
 3 putation of the empirical hillslope length distributions), contained in the folder named
 4 *Catchments*, and with the two different MATLAB scripts that are available at the same
 5 link (together with the DTM input data), named as "*p1-empiricalHillslopeLengthDistributions.m*"
 6 and "*p2-calibrateHyperbolicParam_AllBasins.m*" respectively. The scripts must be placed
 7 in the same location of the folder *Catchments* to work properly. The first script performs
 8 the computation of the empirical distributions from the DTM (for a single specified catch-
 9 ment), while the second one performs the calibration of the hyperbolic parameter (for
 10 all the catchments in a single run). For this reason, the user is asked to run the script
 11 "*p1-empiricalHillslopeLengthDistributions.m*" first, as many time as the possible catch-
 12 ments are, by selecting the proper input catchments and specifying the input variables
 13 (see below). Then it'll be possible to run the second script named "*p2-calibrateHyperbolicParam_AllBasins.m*",
 14 the outputs of which are described at the beginning of the script itself. The second script
 15 does not require any specification of input variables. The following lines of this sections
 16 aim to give some hints on the functioning of the first script instead. The code structure
 17 of "*p1-empiricalHillslopeLengthDistributions.m*" follows these three sections:

- 18 • Input specifications;
- 19 • Import data, morphology indexes and initialization;
- 20 • Network analysis and hillslope distributions.

21 **0.1 Code inputs**

22 Information about the morphology of the catchments is contained in the folder named
 23 *Catchments*. The code automatically imports the information about the DTM of the re-
 24 quested catchment. The user is asked to interact with the first section (named as Input
 25 specification), by properly setting the values of the following variables (at least to select
 26 the desired catchment to be analyzed):

- 27 • *report_iterations*, is a logical variable that should be set equal to *true* to receive
 28 a message in the command window about every network expansion performed by
 29 the code, *false* otherwise;

- 30 • *save_on_file*, is a logical variable that specifies whether the workspace with the vari-
31 ables should be saved at the end of the code and as a backup after a certain amount
32 of iterations (*true*) or not (*false*). It is recommended to set it equal to *true*;
- 33 • *save_after_nIters*, is the integer variable specifying the amount of iterations after
34 which the code will save the workspace variables as backup. The variables are saved
35 at the end of the code regardless of the value of this variable;
- 36 • *catchment_id*, is the integer variable that must be set equal to a value in between
37 1 and 17 (according to the list provided in the code) to select the desired catch-
38 ment;
- 39 • *restart*, is a logical value that specify if you want to continue an old analysis that
40 you had already performed (*true*) or to start a completely new analysis (*false*).
41 It is recommended to set it equal to *true* unless the analysis to perform is really
42 time consuming. To continue an old analysis will automatically skip the compu-
43 tation of the morphometric indexes;
- 44 • *computeAllInfo*, should be set equal to *true* if you want to compute the morpho-
45 metric indexes (as for instance the Gravelius coefficient), *false* otherwise;
- 46 • *preserve_eccentricity*, is a logical variable determining whether to continue to com-
47 pute the elliptic eccentricity from a previously started (and not completed) attempt
48 (*true*), or not (*false*). It is recommended to set it equal to *false* since the compu-
49 tation is generally not heavy for headwater catchments.

50 The second and third sections of the code (*"Import data, morphology indexes and ini-*
51 *tialization"* and *"Network analysis and hillslope distributions"* respectively) don't require
52 any variable specification by the user.

53 **0.2 Code outputs**

54 The results provided by the code are given in MATLAB '-mat' format and they
55 are contained in a folder named as *Results_nameCatchment* which is automatically cre-
56 ated by the code. Two different relevant '-mat' files will be created: the first one is named
57 *totpixel.mat* and contains the value of the amount of pixels of the DTM which belong
58 to the drainage area of the selected catchment outlet (pixel with the highest value of the
59 contributing area in the DTM). The second one is named *Workspace_Final.mat* and it
60 contains all the interesting output variables:

- 61 • dx , is the size of the pixel side in meters;
- 62 • $network_Lengths$, is an array such the i^{th} component corresponds to the length L
- 63 of the channel network at the i^{th} iteration in units of pixels;
- 64 • $branching_Index$, is an array containing the value of a branching index along the
- 65 iterations. The number of branches of all the spatial configurations of the chan-
- 66 nel network can be found as $num_branches = 1./(\text{ones}(\text{size}(branching_Index)) -$
- 67 $branching_Index)$.
- 68 • $distributions_support$, is a matrix, the i^{th} column of which corresponds to the hill-
- 69 slope length ℓ values at which the hillslope distribution has been sampled (the hill-
- 70 slope distribution related to the i^{th} spatial configuration of the channel network);
- 71 • $distributions_w0$, is a matrix, the i^{th} column of which corresponds to the values
- 72 of the hillslope length distribution conditioned to the fact that the river network
- 73 has assumed its i^{th} spatial configuration (the hillslope distribution related to the
- 74 i^{th} spatial configuration of the channel network, which means $\omega_e(\ell, L = L_i)$). The
- 75 ℓ values at which $\omega_e(\ell, L = L_i)$ is evaluated are provided by the i^{th} column of
- 76 the matrix $distributions_support$. Please, note that, despite its name, this vari-
- 77 able is not the known initial condition ω_0 for the hyperbolic model, but rather the
- 78 empirically observed function $\omega_e(\ell, L)$;
- 79 • $distributions_w$, is a matrix analogous to $distributions_w0$ and it is used by the code
- 80 for the computation of the impact coefficient $\alpha(\ell, L)$. Please note that, despite its
- 81 name, this variable does not consist in the hyperbolic model of the hillslope length
- 82 distribution and it is not the empirically observed distribution $\omega_e(\ell, L)$;
- 83 • $distributions_alpha$, is a matrix, the i^{th} column of which corresponds to the val-
- 84 ues of the empirically observed impact coefficient conditioned to the fact that the
- 85 river network has assumed its i^{th} spatial configuration (the i^{th} column consists
- 86 in the function $\alpha(\ell, L = L_i)$). The ℓ values at which $\alpha(\ell, L = L_i)$ is evaluated
- 87 are provided by the i^{th} column of the matrix $distributions_support$.

88 Please note that all the values given in the matrix $distributions_support$ are in units of
 89 pixels, so the user should multiply them by $dx/1000$ to get the corresponding values in
 90 kilometers (and, in that case, the $distributions_w0$ and $distributions_w$ matrices should
 91 be multiplied by $1000/dx$ to preserve the unitary integral of hillslope length distributions).

92 Partial results of the analysis obtained from intermediate backups of the code should not
93 be considered. In particular, the *distributions_w0* matrix from intermediate backups should
94 be multiplied by 2 to get properly normalized distributions.
